Background

- ▶ People use Online Social Networks (OSNs), e.g., Facebook, Flickr, Google+ *etc.* to share contents with their friends

Background

- ▶ People use Online Social Networks (OSNs), e.g., Facebook, Flickr, Google+ *etc.* to share contents with their friends
- ▶ Existing OSNs have a centralized view from outside
 - ▶ Creates content silos, not interoperable with each other
 - ▶ Uses user data for their profit, *e.g.*, in advertisement
 - ▶ Users have to agree to future changes in terms of service

Background

- ▶ People use Online Social Networks (OSNs), e.g., Facebook, Flickr, Google+ *etc.* to share contents with their friends
- ▶ Existing OSNs have a centralized view from outside
 - ▶ Creates content silos, not interoperable with each other
 - ▶ Uses user data for their profit, *e.g.*, in advertisement
 - ▶ Users have to agree to future changes in terms of service
- ▶ How to overcome these shortcomings ?
 - ▶ Decentralize the OSN infrastructure. Do social networking in a more P2P way
 - ▶ Diaspora, PeerSon, SafeBook, SuperNova, Cachet, PrPl are a few approaches to decentralize OSN

The Problem

- ▶ One important question still remains to be answered
 - ▶ *How to ensure 24 x 7 content availability with minimal replication overhead ?*
- ▶ Existing Solutions
 - ▶ *The DOSNs are still in early stage and does not provide enough discussion about ensuring availability*

Our Contribution

- ▶ We propose
 - ▶ The notion of β -availability
 - ▶ At least beta members of a replication group will be online
 - ▶ S-DATA protocol
 - ▶ A time based replication group formation protocol to ensure β -availability
 - ▶ Uses structured overlay, *i.e.*, Distributed Hash Table (DHT) to maintain replication groups, advertise availabilities, and resolve queries

Availability Representation

a_{ix} = the probability of user x
being online during time slot x , 1
 $\leq x \leq 24$

Availability vector (A)

0.2	0.1	...	0.9	0.9	...	0.1	0.0
-----	-----	-----	-----	-----	-----	-----	-----

Availability Representation

a_{ix} = the probability of user x
being online during time slot x , 1
 $\leq x \leq 24$

- Encoded \mathbf{A} into Linear Binary Code
- Take pair wise average in A
 - Encode each element to 2-bit binary

Availability vector (A)

0.2	0.1	...	0.9	0.9	...	0.1	0.0
-----	-----	-----	-----	-----	-----	-----	-----

Availability pattern

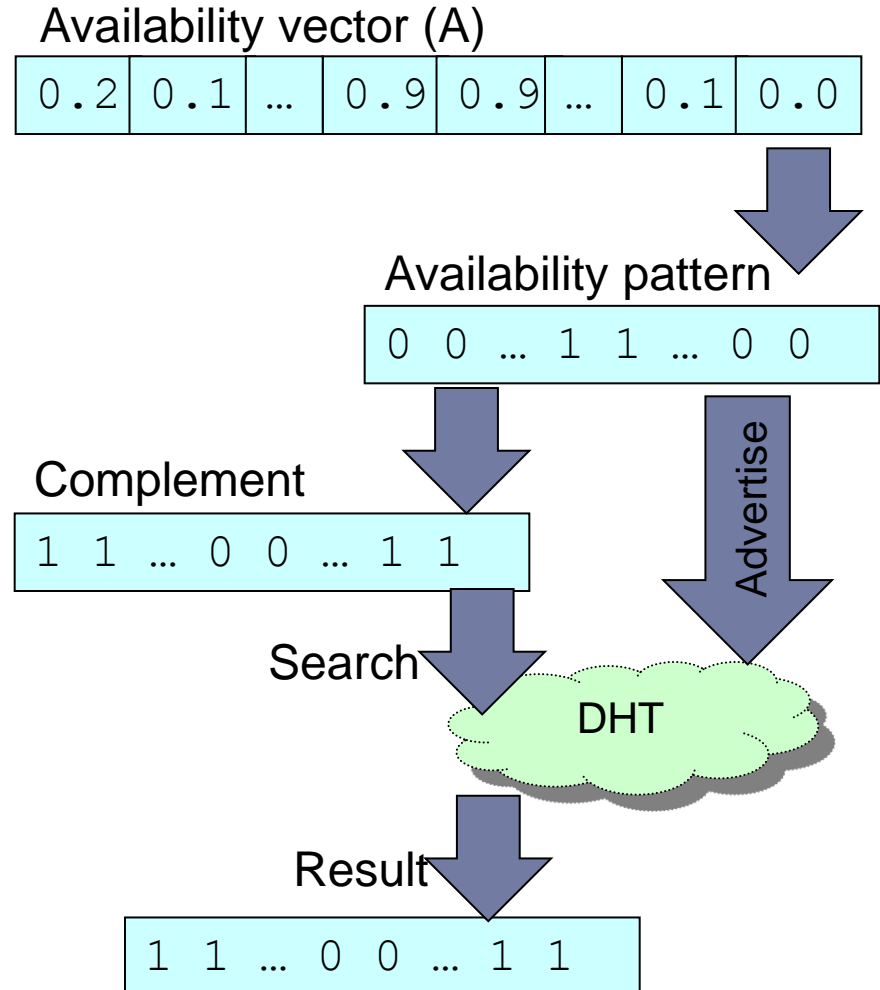

0	0	...	1	1	...	0	0
---	---	-----	---	---	-----	---	---

Availability Representation

a_{ix} = the probability of user x being online during time slot x , $1 \leq x \leq 24$

- Encoded \mathbf{A} into Linear Binary Code
- Take pair wise average in \mathbf{A}
 - Encode each element to 2-bit binary

System Architecture

- ▶ Three major conceptual components
 - ▶ Group Index Overlay (GIO)
 - ▶ Content Index Overlay (CIO)
 - ▶ Replication Groups

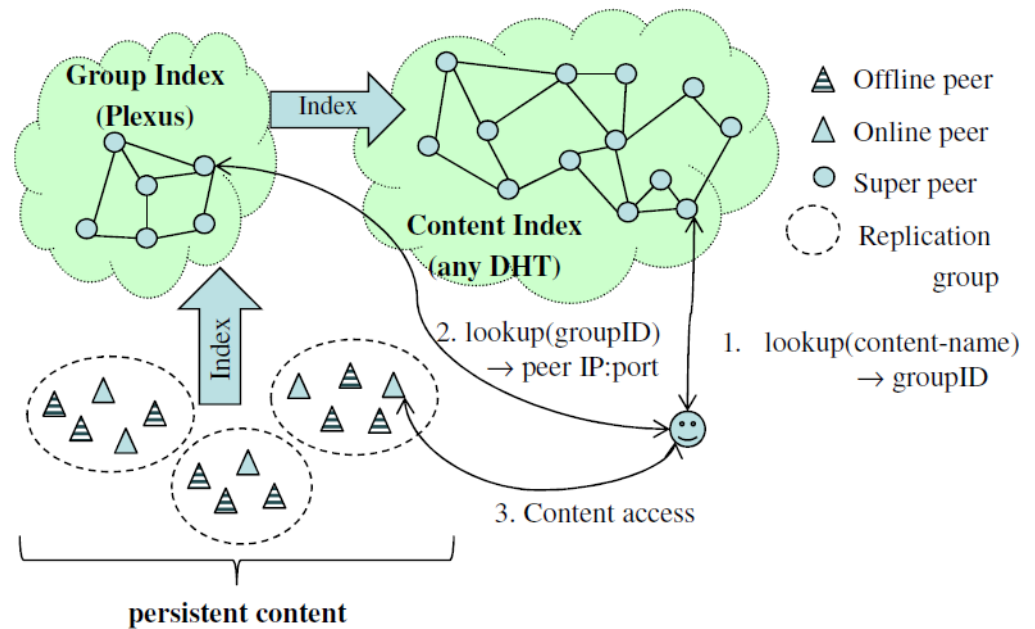

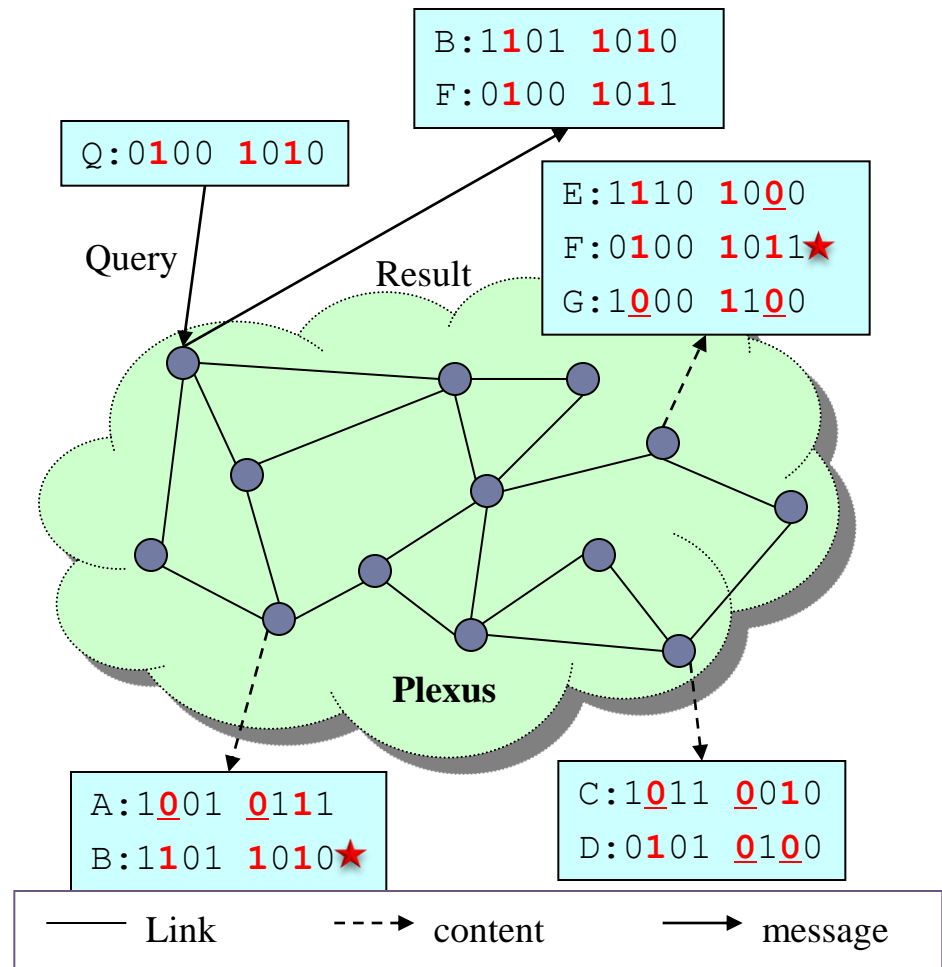

Fig. 1. Conceptual Architecture of S-DATA

System Architecture: GIO

- ▶ Stores mapping for group ID to its member peers
- ▶ Acts as distributed matchmaking agent
 - ▶ Given a user's availability pattern, find other users with complementary availability patterns
- ▶ Given a user's availability bit pattern, we need to perform partial matching in the GIO DHT
 - ▶ Till date, only Plexus (*Ahmed et al. TON 2009*) is known to have this capability
 - ▶ Therefore, we use Plexus as GIO

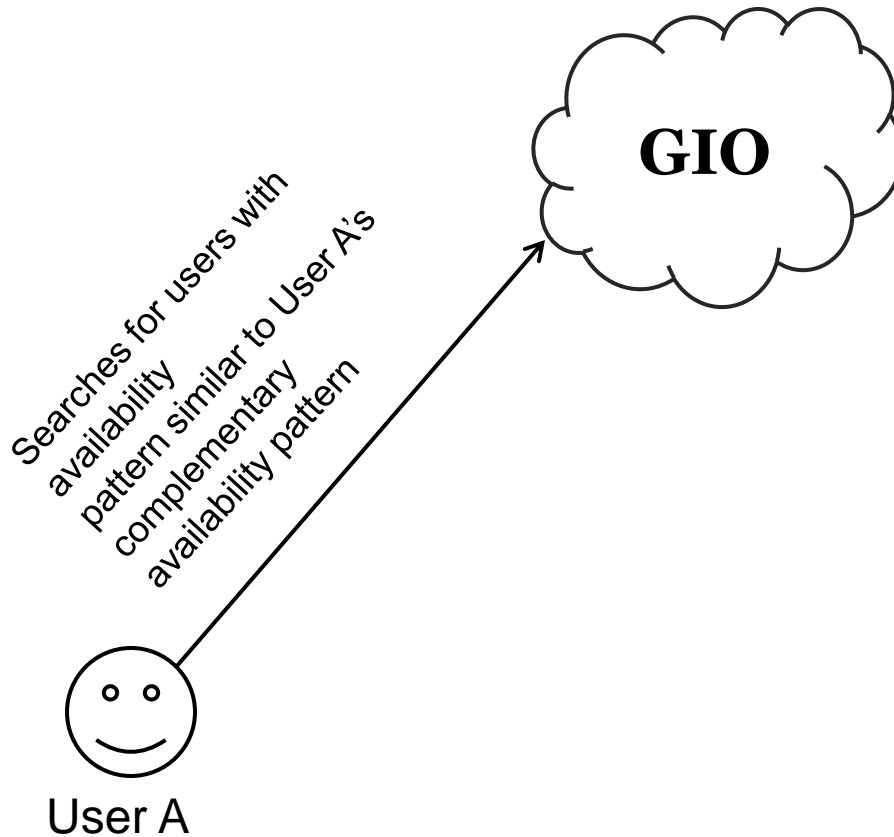

System Description: CIO and Replication Groups

- ▶ **CIO**
 - ▶ Maps content names to group IDs
 - ▶ Out of the paper's scope
- ▶ **Replication Groups**
 - ▶ Users are clustered based on their diurnal availability patterns
 - ▶ All members of the group replicate each others contents

Protocol Description

Protocol Description

Performs partial search in Plexus DHT to find users with availability pattern similar to User A's complementary availability pattern

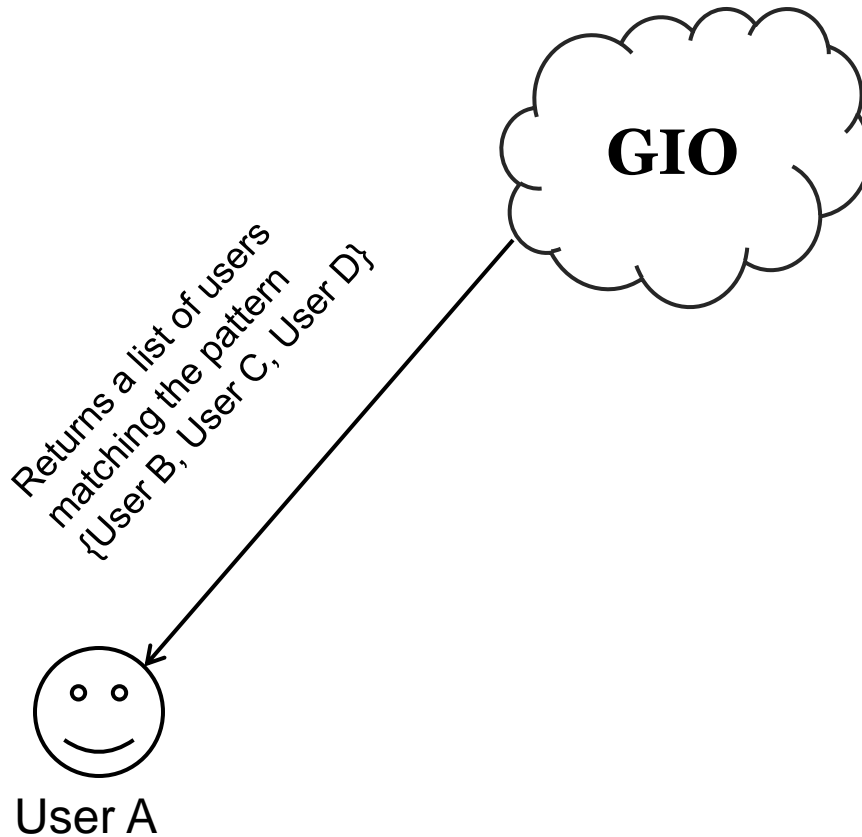

User A

User B

Protocol Description

Protocol Description

Selects User B, since User B's availability pattern has minimum hamming distance from the desired pattern

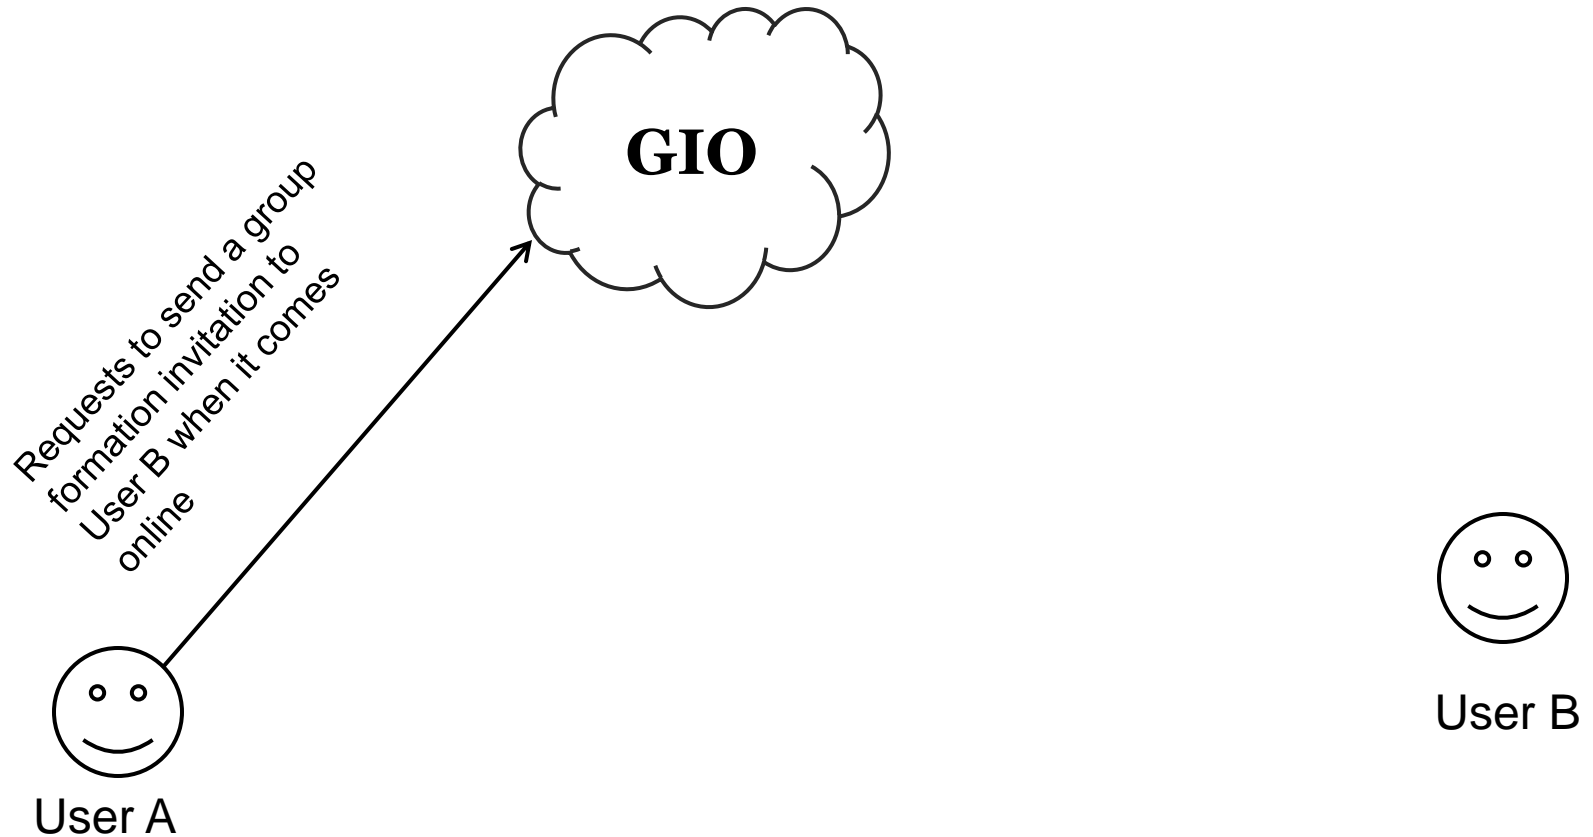

User A

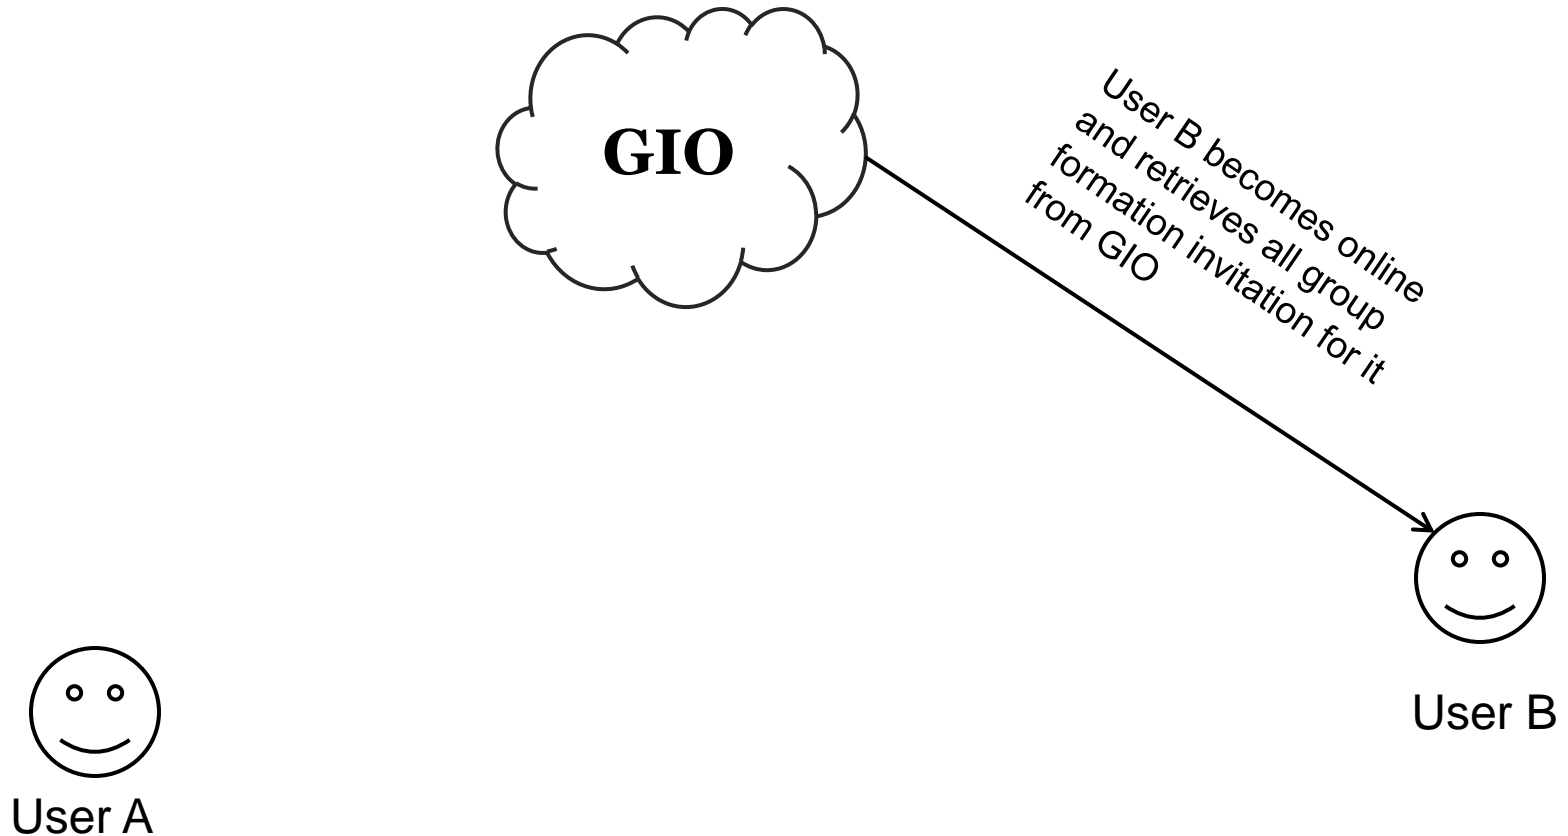

User B

Protocol Description

Protocol Description

Protocol Description

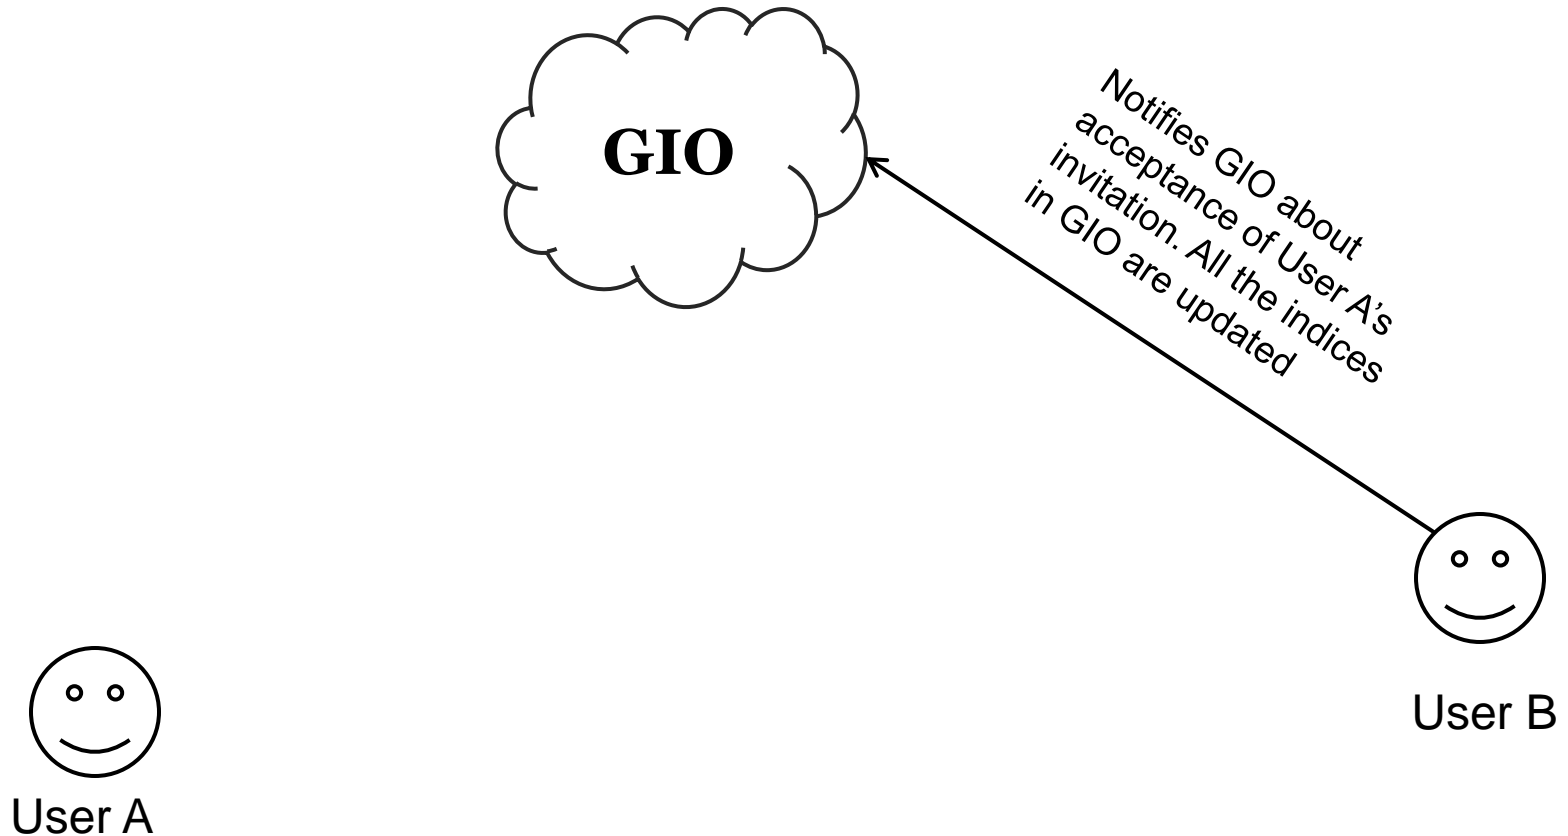

User A

User B selects the best invitation and discards the rest

User B

Protocol Description

Evaluation

- ▶ **Setup**
 - ▶ We used **PeerSim** to simulate the protocol
 - ▶ **Pareto distribution** was used to generate availability vectors
 - ▶ **Extended Golay Code** used for encoding
- ▶ **We measured**
 - ▶ **Normalized Messaging Overhead**
 - ▶ Number of invitations required for forming a single group
 - ▶ Compared it with Random, Central and Unstructured grouping approaches
 - ▶ **System Availability**
 - ▶ Probability of having at least one online user from a group at any given time
 - ▶ **Effect of Failure**
 - ▶ Probability of having at least one member of a group online when certain percentage of users do not become online in their expected online slot

Evaluation: Results

- ▶ Normalized Messaging Overhead
 - ▶ Network size increased from **5000** to **30000** in steps of **5000**
 - ▶ Central approach is baseline
 - ▶ Our approach has overhead very close to the central approach
 - ▶ Very little effect of the network size

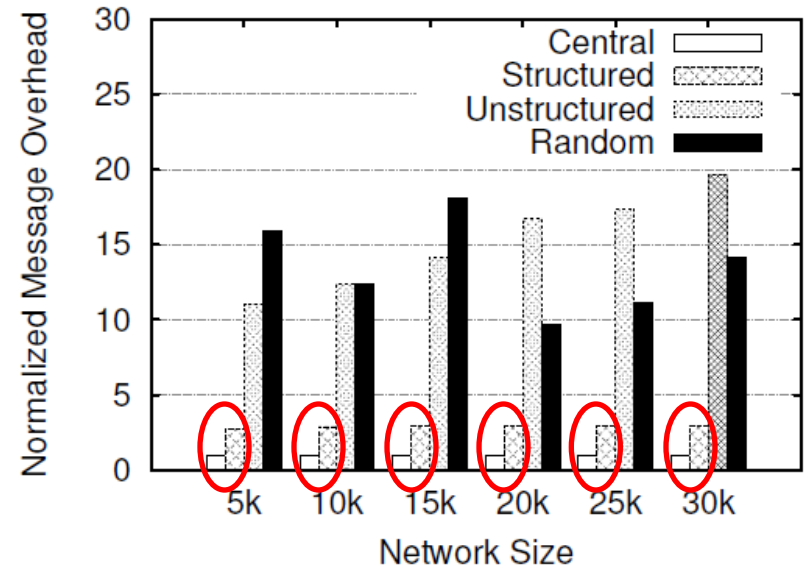

Fig. 3. Normalized Message Overhead

Evaluation: Results (cont..)

▶ System Availability

- ▶ A **significant improvement** in system availability when β **increases from 1 to 2**
- ▶ Improvements for higher beta are very less

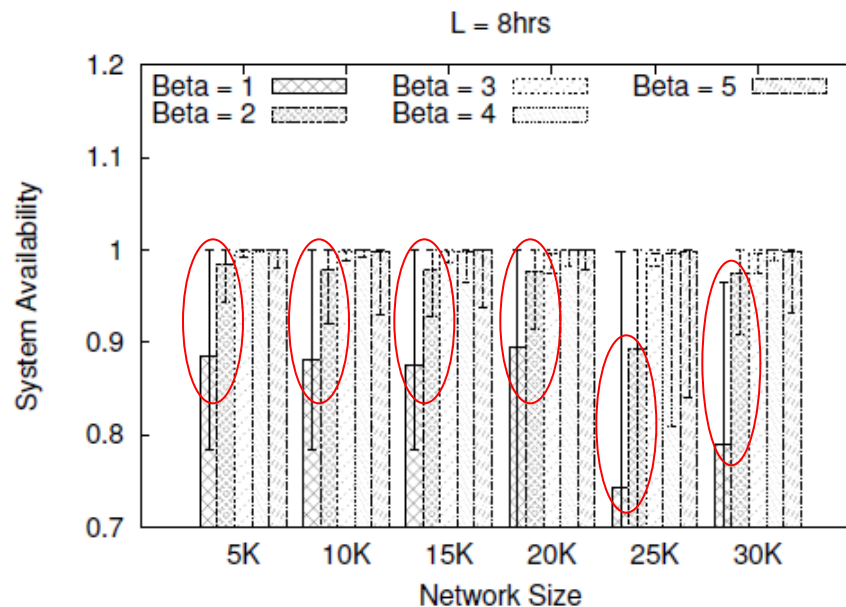

Fig. 4. System Availability

Evaluation: Results (cont..)

► Effect of Failure

- For **beta** ≥ 2 , more than **93%** groups are available even after **50% users failing** to be online in their expected period

Fig. 6. Effect of Failure on System for Different β

Evaluation: Take Away

- ▶ **$\beta = 2$** is a good operating point
 - ▶ Can achieve high system availability
 - ▶ Lower overhead
 - ▶ **93% groups** are online even after **50% nodes failing**

Conclusion & Future Work

- ▶ Ensuring availability in a decentralized social network with not so stable users and taking the social relationship of the peers is challenging.
- ▶ We take a **first step** towards solving the problem and **solve it without considering social relationships**.
- ▶ We also **introduce** the notion of **beta-availability**.
- ▶ In the **next step** we are considering **social relationships**.
- ▶ Simulation results show **$\beta = 2$ is a good operating point**.
